

PP3S Diary Group E

David A

May 2026

1 Week 1

In the first week of our project, we mainly focused on organizational tasks. We introduced ourselves to each other, talked about our previous experience and discussed who would take on which responsibilities. We also chose our project manager and divided the group into frontend and a backend team. After that we talked about the general project vision and agreed on some basic structures we want to work with. Therefore we also discussed which frameworks and technologies could be useful for our project. The frontend team started working on the basic outer structure of the application, while the backend team began researching important topics so that everyone would have a similar level of knowledge when starting programming. (Ella)

Last Thursday, our group had our first official meeting. We got to know each other a bit better and started discussing the overall structure of the project. We also briefly talked about how we plan to collaborate and organize our workflow in the coming weeks. We have decided to use TypeScript as our main programming language. Since I have never used TypeScript before, I've started watching tutorials and going through some learning materials to gradually get familiar with it.

I've also developed some interest in the database part of the project. Since I have some prior experience with SQL, I'm considering focusing more on this area next week. I might try to create an initial outline for the database design to help structure our ideas more clearly and support the team's planning process.

We will likely be using PostgreSQL as the database for the project. I've also started learning it this week, and I'm looking forward to exploring it further and gaining a better understanding of how it can be applied in our system. (Yifan)

In the first group meeting, we discussed the tech-stack among other things. We decided to use a Typescript-based one. I created with David Assheuer the GitHub repository and initialized the first backend architecture with an example module and a basic database schema. This was done to help our team members have a first glance on the usage of our tech-stack. Oliver and I were chosen

to work on the frontend and UI/UX design of the web application. I was also tasked to have an oversight for the hosting of our project. In the next group meeting, we planned out the backend and its system design. We focused on the modules/endpoints that were extracted from the given requirements and defined the API contracts between each module. This system design was then drawn in an overview on a whiteboard. After the meeting, Oliver and I started to work on the frontend. We sketched out a theme for the UI and designed the first dashboard page with mock data. (David)

After our group meeting, David and I started going over the basics of the frontend UI/UX design and architecture. While he started designing the initial design language, I researched a solution for authentication. After considering a few options, we've decided to go ahead with BetterAuth, as it is open-source, framework-agnostic, and most importantly, self hosted in our PostgreSQL database. Following that, I initialized BetterAuth in the Hono backend and generated a migration for the local database. Lastly, I planned how the actual Login/Signup flow will look like, and how it will interact with the auth API. The actual implementation of that will be done until the end of the week. (Oliver)

The first few times we met were spent mainly on deciding on which technologies to use and a general idea of the architecture, which we decided would be monolithic, at least at first. After deciding on Bun, Hono, Orval, Drizzle, PostgreSQL and Betterauth on the backend, and SvelteKit on the frontend, we set up a GitHub repository as well as a Linear board for tracking and assigning tasks. I have yet to do any coding, but my first assigned task is writing a solid client for our stock information API, which I will do until Thursday. Our initial draft of the backend architecture included a few modules, their interactions, responsibilities and features. (Moritz)

I started by going over TypeScript and learning the basic concepts that will be useful for our project. This includes types, interfaces, and general structure, to better understand how we will use it in both frontend and backend development.

Our next meeting is expected on Thursday, where we will go into more detail about the sub-structure of the system and how the components will be organized. (Mehmet)

At the start of the project, our main focus this week was getting organized as a team and understanding what we want to build. We spent time introducing ourselves, sharing our experience, and deciding how to split the work between frontend and backend. We also agreed on using TypeScript as our main programming language, so I began learning the basics since it's new to me.

The backend team worked on planning the system architecture, including

how different components like the API, transaction logic, and overall backend structure should interact. I followed the discussions to understand the system and how everything fits together.

In the next weeks, I want to get more involved in the backend development, especially in implementing core logic like API endpoints and transaction handling. Overall, this week helped me get a solid overview of the project and prepare for contributing more actively once development begins. (Tekle)

Last week, we discussed the project at a high level, assigned different parts to each team, and created some diagrams outlining how the project should be structured. The frontend team started with the basics, while the backend team began learning and refreshing their knowledge of the specific technologies that will be used. As discussed, it currently seems that I will mainly be involved in the backend part, while also assisting with the frontend if need be. This week, I started going through tutorials on Hono, Drizzle, and TypeScript ahead of our next meeting on Thursday, May 7th. I've only worked with TypeScript on a basic level before, so I'm mainly refreshing and strengthening my understanding of it. (Doruk)

The first two weeks, we determined how we want to organize and work as a team. We decided to meet in person each Thursday at noon. For communication we set up a Signal channel, GitHub for code hosting, Linear for issue tracking, and tldraw as a whiteboard. We decided on a tech stack and assigned roles based on our interests and prior knowledge. Last week we then sketched out the backend architecture based on the requirements and assigned the first big coding tasks. As a PM I relied on Signal's voting feature to make remote group decisions and feedback easy. I also updated everyone on upcoming deadlines and organizational tasks such as the diary. (David A)
