

PP3S Diary 3

Group E

May 2026

Like planned last week, I built the login and signup pages for the frontend, connected to the BetterAuth API through a same origin Vite proxy. That was necessary so session cookies work without CORS. This will need to be changed when going into production, meaning proper CORS will be needed. I had to fix a couple of backend issues that were hindering the sign up flow: the Drizzle adapter wasn't seeing the auth schema, and the .env file wasn't being loaded into the Docker container. What's new from last week, is that the auth is now actually fully wired end to end: the signed in user shows up in the sidebar with a sign out button and the mock user is gone (the app still defaults to mock stock data until the backend exposes a per user account endpoint). PR is now open against dev and is awaiting review by David Brandes. (Oliver)

This week I mainly refined the database schema based on the feedback and discussions from last week. I adjusted several schema details, improved foreign key structures, and cleaned up the module organization.

I also improved several enums in the trade schema to make status handling and rule definitions more explicit and safer on the database level. In addition, I reviewed indexes and checked schema consistency across modules to avoid naming and relation conflicts later during integration.

Another major task this week was resolving backend CI issues. Most warnings and errors were fixed, including import path cleanup, unused imports, and formatting issues. I also reviewed the compatibility between the database layer and the Better Auth setup currently used by the team. (Yifan)

For this week, we talked in a standup/sync meeting about what each group member has implemented and what struggles they had. We clarified questions for some implementations and scanned over the GitHub Pull Requests. Afterwards, David (PM) and I code-reviewed every Pull Request and either approved the integrations or request changes. By reading all the implementations, I gained a better oversight how modules should talk between each other and what contracts are still missing. The next days after, Oliver showed me his Better Auth implementation and I reviewed it. Afterwards, I created a better UI and UX theme for the frontend, as we have been using Shadcn components scatteringly. I also created the frontend pages for the approved changes from Tekle and Ella. (David)

During the third week, Ella and I structurally implemented the user and leadership modules. For each module, we created schema, routes, and service files. We also added a user profile database table that can be joined by ID with the BetterAuth module. After that, we presented and discussed our implementation in a group meeting. (Tekle)

This week, I focused on backend tutorials which could be related to the technologies used in our project, especially Hono, Zod validation, and basic backend module structure. I recreated and tested simple GET and POST endpoints locally to better understand routing, request validation, and service logic. I also familiarized myself with the Git workflow used in the project, including feature branches and Pull Requests. (Mehmet)

During this week, after the completion of our first task with Mehmet, I focused on continuing my learning about the technologies that we are planning to use, and tutorials of Backend programming. Also, I worked on understanding our progress on the project and again went over the GET and POST endpoints that we had done last week with Mehmet. (Doruk)

This week, I had very little time and didn't get anything substantial done. I did think about the structure and technologies/patterns to be used for the sync module though, which I will begin implementing next week. (Moritz)

I reviewed all the PRs together with David. We gave feedback and merge two excellent PRs. I also did the usual PM tasksd like last week. (David)

The third week Tekle and I structurally implemented the user and leadership modules. For each module we created a schema, routes and service file. The routes file defines how the functions defined in services can be used, validated by the schema file. We also added a user profile database table that can be joined by id with the betterAuth module. After that we presented and discussed our implementation in a group meeting. The next step is to make a few small adjustments, for example regarding the formatting of comments in the code. (Ella)
