

PP3S Diary 10

Group E

Jul 2026

For this weeks hackathon, I have fixed an unnoticed external subrequest bug for the Cloudflare worker, which made us unable to request the uni-provided API. I added a proxy worker to whitelist a fetch call to a direct IP address. I also added a backfill data flow process which routinely fetches the data for the 11900 tickers and polished the performance chart history for stock details. (David B.)

This week I focused on checking whether the requirements of the task are matched. Then I worked on creating the poster in LaTeX for the final presentation. (Ella)

I worked on a couple of frontend issues, mainly related to optimizing the amount of fetching from the backend, to reduce the load of our cloudflare instance (since we are on the free tier and only have a limited amount of free requests). Furthermore, I dealt with an issue of better auth, where their password hashing was not optimized for running edgeless. I had to write my own very simple hashing (found an official issue on their github page). (Oliver)

This week I worked on the frontend branding of our project. I added the ScaleRepublic logo to the login and signup pages and integrated the new branding into the dashboard sidebar. I adjusted the layout for both expanded and collapsed sidebar modes and made sure the logo works well in dark mode. After testing the changes, pushed the branch to GitHub, and prepared a pull request for review. Also checked the project with the Copilot to identify missing dependencies and possible API-related issues. (Mehmet)

This week, we held a hackathon on the weekend. We implemented the limit orders in the backend, wrote a simple UI for them, and implemented a notification section to see when they execute. We also performed a major refactor of our frontend's server-caching state solution, going from hand-rolled caching, polling and state mutations to tanstack query, also fixing RPC type inference on the way so we can infer frontend types from the backend routes. Overall, this decreased size but primarily complexity of the frontend codebase by quite a bit. (Moritz, Yifan)

Last week we held a hackathon at Davids place. I managed Linear and made sure all issues were covered. I also added Stock information, but the module. I also added neutral styling for zero portfolio change, removed unused notification settings from the frontend, refactored cluttered frontend Svelte code into shared components and improved buy/sell trade sheets with balance visibility. And I worked on the poster. (David)

This week, we fixed the remaining issues and worked on the poster and presentation.(Tekle)

This week, I implemented the backend function for deleting a user portfolio and revoking the active trade orders. After finishing that, I did some implementations for the login page, namely adding password requirements for a valid password. (Doruk)
